Among the various studies conducted, the most common one is the use of the "Baker-Parker" method, which involves the use of a specialized instrument to measure the thickness of the skin. This method is widely used because it is relatively simple and can be performed on a large number of subjects. However, it has been found to be less accurate than other methods, particularly in the case of children and young adults. Other methods, such as the use of ultrasonic waves or the measurement of the skin's electrical resistance, have been found to be more accurate but are more complex and expensive. Therefore, the choice of method depends on the specific requirements of the study and the resources available.
